A Local Context

In this document, we use 0-based numbering for numbering bases, i.e, in a strand of length l, the first nucleotide at the 5' end of the strand is numbered 0 and the last nucleotide at the 3' end of the strand is indexed l-1.

To determine the local context of a base pair forming or breaking in a pseudoknot-free structure, we use Algorithm 1. This algorithm uses dot-parens-plus notation to represent a secondary structure (state), which consists of '(', ')', '.', and '+'. Matching parentheses represent bases which have formed a base pair, a dot represents a free base pair, and a plus represents a nick between strands. For example, '(((((((+))))))' means that bases 0, 1, 2, 3, 4, and 5 of the first strand are paired to bases 5, 4, 3, 2, 1, and 0 of the second strand, respectively. When all base pairs between strands break, we replace the plus sign by a space. For example, '......' means that no base pair is formed.

Algorithm 1: Find the local context of a base pair forming or breaking

```
Function LocalContext (s_i, s_j)
Input: state s_i and state s_j, which differ in exactly one base pair
Output: \langle l, r \rangle, which is the local context of the base pair breaking or forming
d_i \leftarrow dot-parens-plus notation of s_i
d_j \leftarrow dot-parens-plus notation of s_j
Insert '*' at the start and end of d_i and d_j, before and after all '+' signs, and also before and after every space
(p_1, p_2) \leftarrow \text{the two positions where } d_i \text{ and } d_j \text{ differ}
l \leftarrow \text{HalfContext } (d_i, p_i - 1, p_j + 1) \qquad // \text{Algorithm 2}
r \leftarrow \text{HalfContext } (d_i, p_i + 1, p_j - 1)
\text{return } \langle l, r \rangle
```

Algorithm 2: Find the half context on one side of a base pair forming or breaking

```
Function LocalContext(d, p_i, p_j)
            c_i \leftarrow d[p_i]
             c_j \leftarrow d[p_j]
            if c_i = (' \text{ and } c_i = ')' then
                        counter \leftarrow 0
                         for k in [p_i, p_j] do
                                     if s[k] = ('then counter \leftarrow counter + 1)
                                      else if s[k] = ')' then counter \leftarrow counter - 1
                                     if counter = 0 then
                                                  if k = p_i then return stack
                                                  else return stack+stack
            if (c_i = (' \text{ and } c_i = (' \text{ }) \text{ or } (c_i = ')' \text{ and } c_i = ')') or (c_i = ')' and (c_i = (' \text{ }) \text{ }) then return stack+stack
            if (c_i = (') \text{ and } c_j = (')') or (c_i = (')') and c_j = (')' or (c_i = (')') or (c_i = (')') or (c_i = (')')
             then return stack+loop
            if c_i = (' and c_j = (*)' or (c_i = ')' and c_j = (*)' or (c_i = (*)') o
             then return stack+end
            if (c_i = `.' \text{ and } c_j = `*') or (c_i = `*' \text{ and } c_j = `.') then return loop+end
            if c_i =  '*' and c_j =  '*' then return end
            if c_i = `.' and c_j = `.' then return loop
```

B Interacting DNA Strands State Space

To generate the state space we use Algorithm 3 in combination with a reaction-specific set of initial states S_{init} and final states S_{final} and a reaction-specific function that returns neighboring states for a state s, NeighborStates(s). Algorithm 3 uses a breadth-first search approach: initially, the queue Q and candidate state space S_{init} are composed of just the initial states. For every state in the queue, unexplored successor states are added to the candidate state space and then queued for exploration. In this paper, we use only one initial state and one final state per reaction.

Next, we explain the state space we used specific to different types of reactions in our dataset.

Algorithm 3: Generate state space

B.1 Hairpin Closing and Opening

Let l be the length of the hairpin strand and let m < l/2 be the length of the stem in the fully closed position. Each state is represented by a tuple $\langle p_i, p_j \rangle$, where $0 \le p_i \le p_j \le m$. The tuple indicates that the bases p_i to $p_j - 1$ are paired with bases $l - p_j$ to $l - p_i - 1$ respectively, and no other base pairs are formed. Algorithm 4 describes the neighbors of a hairpin state s. The state space of hairpin opening and closing are equal, except that the initial and final states are swapped. In hairpin closing, in the initial state $(S_{\text{init}} = \{\langle 0, 0 \rangle\})$, no base pairs have formed. In the final state $(S_{\text{final}} = \{\langle 0, m \rangle\})$, all base pairs have formed.

Algorithm 4: Find possible neighbors of a hairpin state s

```
Function NeighborStates(s)
       \langle p_i, p_i \rangle \leftarrow s, \mathcal{N} \leftarrow \emptyset
      if \langle p_i, p_i \rangle = \langle 0, 0 \rangle then
            for p_n \in [0, m-1] do
                  \mathcal{N} \leftarrow \mathcal{N} \cup \langle p_n, p_n + 1 \rangle
      else
        | \mathcal{N} \leftarrow \mathcal{N} \cup \langle p_i - 1, p_j \rangle \cup \langle p_i + 1, p_j \rangle \cup \langle p_i, p_j - 1 \rangle \cup \langle p_i, p_j + 1 \rangle 
      for s' \in \mathcal{N} do
       if p_i = p_j then \mathcal{N} \leftarrow \mathcal{N} \setminus s' \cup \langle 0, 0 \rangle
      for s' \in \mathcal{N} do
        if !AllowedState(s') then \mathcal{N} \leftarrow \mathcal{N} \setminus s'
      return \mathcal{N}
Function AllowedState(s')
      \langle p_i, p_j \rangle \leftarrow s'
      if !(0 \le p_i \le p_j \le m) then return False
      return True
```

B.2 Helix Association and Dissociation

Let l be the length of a strand in the helix. Each state is represented with a tuple $\langle p_i, p_j \rangle$, where $0 \le p_i \le p_j \le l$. The tuple indicates that all bases numbered p_i to $p_j - 1$ in one strand have paired with bases numbered $l - p_j$ to $l - p_i - 1$ in the other strand, respectively, and there are no other base pairs in the state. Algorithm 5 describes the neighbors of a helix state s. The state space of helix association and dissociation are equal, except that the initial and final states are swapped. In helix association, in the initial state $(S_{\text{init}} = \{\langle 0, l \rangle\})$, no base pairs have formed between the two strands. In the final state $(S_{\text{final}} = \{\langle 0, l \rangle\})$, all base pairs have formed between the two strands.

Algorithm 5: Find possible neighbors of a helix state s

```
Function NeighborStates (s)
       \langle p_i, p_j \rangle \leftarrow s, \, \mathcal{N} \leftarrow \emptyset
       if \langle p_i, p_j \rangle = \langle 0, 0 \rangle then
              for p_n in [0, l-1] do
                \mathcal{N} \leftarrow \mathcal{N} \cup \langle p_n, p_n + 1 \rangle
       else
          | \mathcal{N} \leftarrow \mathcal{N} \cup \langle p_i - 1, p_j \rangle \cup \langle p_i + 1, p_j \rangle \cup \langle p_i, p_j - 1 \rangle \cup \langle p_i, p_j + 1 \rangle 
       for s' \in \mathcal{N} do
            if p_i = p_j and p_i \neq 0 then \mathcal{N} \leftarrow \mathcal{N} \setminus s' \cup \langle 0, 0 \rangle
       for s' \in \mathcal{N} do
            if !AllowedState(s') then \mathcal{N} \leftarrow \mathcal{N} \setminus s'
      return \mathcal{N}
Function AllowedState(s')
       \langle p_i, p_j \rangle \leftarrow s'
       if !(0 \le p_i \le p_j \le l) then return False
       return True
```

B.3 Bubble Closing

Let l be the length of the hairpin strand, m < l/2 be the length of the stem in the fully closed position, and f be the position where a bubble is formed. Each state is represented with a tuple $\langle p_i, p_j \rangle$, where $0 < p_i < p_j < m$. The tuple indicates that all bases numbered 0 to $p_i - 1$ have paired with bases numbered $l-p_i$ to l-1, respectively, and all bases numbered p_j to m-1 have paired with bases numbered l-m to $l-p_j-1$, respectively, and there are no other base pairs in the state. Algorithm 6 describes the neighbors of a bubble closing state s. In the initial state ($S_{\text{init}} = \{\langle f-1, f \rangle \}$), all base pairs in the hairpin stem have formed except for a bubble of size 1 in the stem at position f. In the final state ($S_{\text{final}} = \{\langle 0, m \rangle \}$), all base pairs have formed.

Algorithm 6: Find possible neighbors of a bubble state s

```
Function NeighborStates (s)
 \begin{vmatrix} \langle p_i, p_j \rangle \leftarrow s, \, \mathcal{N} \leftarrow \emptyset \\ \mathcal{N} \leftarrow \mathcal{N} \cup \langle p_i - 1, p_j \rangle \cup \langle p_i + 1, p_j \rangle \cup \langle p_i, p_j - 1 \rangle \cup \langle p_i, p_j + 1 \rangle \\ \text{for } s' \in \mathcal{N} \text{ do} \\ | \text{ if } p_i = p_j \text{ and } p_i \neq f \text{ then } \mathcal{N} \leftarrow \mathcal{N} \setminus s' \cup \langle f, f \rangle \\ \text{for } s' \in \mathcal{N} \text{ do} \\ | \text{ if !AllowedState}(s') \text{ then } \mathcal{N} \leftarrow \mathcal{N} \setminus s' \\ \text{return } \mathcal{N} \end{vmatrix} 
Function AllowedState(s')
 \begin{vmatrix} \langle p_i, p_j \rangle \leftarrow s' \\ \text{if } !(0 < p_i \leq f \leq p_j < m) \text{ then } \text{return False} \\ \text{return True} \end{vmatrix}
```

B.4 Toehold-mediated 3-way Strand Displacement

Let l be the length of the substrate. For simplicity and without loss of generality, let l also be the length of the invader, m be the toehold length, and l-m be the length of the incumbent. Each state is represented with a tuple $\langle p_i, p_j, p_k, p_l \rangle$, where $0 \le p_i \le p_j \le p_k \le p_l \le l$ and $p_k \ge m$. The tuple indicates that all bases numbered p_i to $p_j - 1$ in the substrate have paired with bases numbered $l-p_j$ to $l-p_i-1$ in the invader, respectively, all bases numbered p_k to p_l-1 in the substrate have paired with bases numbered $l-p_l$ to $l-p_k-1$ in the incumbent, respectively, and there are no other base pairs in the state. Algorithm 7 describes the neighbors of a toehold-mediated 3-way strand displacement state s. In the initial state $(S_{\text{init}} = \{\langle 0, 0, m, l \rangle \})$, the substrate is completely attached to the incumbent, but completely de-attached from the invader. In the final state $(S_{\text{final}} = \{\langle 0, l, l, l \rangle \})$, the substrate is completely de-attached from the incumbent, but completely attached to the invader. Algorithm 8 adapts algorithm 7 for toehold-mediated 3-way strand displacement with mismatches between the invader and the substrate.

Algorithm 7: Find possible neighbors of a toehold-mediated 3-way strand displacement state s

```
Function NeighborStates (s)
                      \langle p_i, p_j, p_k, p_l \rangle \leftarrow s, \mathcal{N} \leftarrow \emptyset
                     if p_i = p_j then
                                          for p_n in [0, p_k - 1] do
                                                            \mathcal{N} \leftarrow \mathcal{N} \cup \langle p_n, p_n + 1, p_k, p_l \rangle
                      else
                                           \mathcal{N} \leftarrow \mathcal{N} \cup \langle p_i - 1, p_j, p_k, p_l \rangle \cup \langle p_i + 1, p_j, p_k, p_l \rangle \cup \langle p_i, p_j - 1, p_k, p_l \rangle \cup \langle p_i, p_j + 1, p_k, p_l \rangle \cup \langle p_i, p_j, p_k - p_l \rangle \cup \langle p_i, p_j - p_l \rangle 
                                         1, p_l \rangle \cup \langle p_i, p_j, p_k + 1, p_l \rangle \cup \langle p_i, p_j, p_k, p_l - 1 \rangle \cup \langle p_i, p_j, p_k, p_l + 1 \rangle
                     for s' \in \mathcal{N} do
                                           if p_i = p_j and p_i \neq 0 then \mathcal{N} \leftarrow \mathcal{N} \setminus s' \cup (0, 0, p_k, p_l)
                                          if p_k = p_l and p_k \neq l then \mathcal{N} \leftarrow \mathcal{N} \setminus s' \cup \langle p_i, p_j, l, l \rangle
                     for s' \in \mathcal{N} do
                                  if !AllowedState(s') then \mathcal{N} \leftarrow \mathcal{N} \setminus s'
                    return \mathcal{N}
Function AllowedState(s')
                      \langle p_i, p_i, p_k, p_l \rangle \leftarrow s'
                     if !(0 \le p_i \le p_j \le p_k \le p_l \le l \text{ and } p_k \ge m) then return False
                     if p_i = p_j and p_k = p_l then return False
                          // Further prune the state space
                     if (0 < m < p_k) and (p_i \neq 0 \text{ or } p_j < p_k - 1) then return False
                     if p_k - p_j > m + 2 then return False
                      return True
```

B.5 Toehold-mediated 4-way Strand Exchange

Let complex be the first helix and complex1 and complex2 be the two strands in this helix. Let reporter be the second helix and reporter1 be the strand in this helix that is complementary to complex1 and reporter2 be the strand in this helix that is complementary to complex2. Let l be the length of the helices excluding their toehold. For simplicity and without loss of generality, let n be the toehold length of complex1 and complex1 and complex1 and let complex1 be the toehold length of complex2 and complex2. Each state is represented with a tuple complex1 and complex1 have paired with a tuple indicates that all bases numbered complex1 have paired with bases numbered complex2 have paired with bases numbered complex3 have paired with bases numbered complex4 have paired with bases numbere

Algorithm 8: Find possible neighbors of a toehold-mediated 3-way strand displacement state s that has a mismatch between the invader and the substrate

```
Function NeighborStates (s)
       \langle p_i, p_j, p_k, p_l \rangle \leftarrow s, \mathcal{N} \leftarrow \emptyset
      if p_i = p_j then
             for p_n in [0, p_k - 1] do
                    if p_n \neq mp then
| \mathcal{N} \leftarrow \mathcal{N} \cup \langle p_n, p_n + 1, p_k, p_l \rangle
             \mathcal{N} \leftarrow \mathcal{N} \cup \langle p_i, p_j, p_k - 1, p_l \rangle \cup \langle p_i, p_j, p_k + 1, p_l \rangle \cup \langle p_i, p_j, p_k, p_l - 1 \rangle \cup \langle p_i, p_j, p_k, p_l + 1 \rangle
             if p_i - 1 \neq mp then \mathcal{N} \leftarrow \mathcal{N} \cup \langle p_i - 1, p_j, p_k, p_l \rangle
             else \mathcal{N} \leftarrow \mathcal{N} \cup \langle p_i - 2, p_j, p_k, p_l \rangle
             if p_i + 1 \neq mp then \mathcal{N} \leftarrow \mathcal{N} \cup \langle p_i + 1, p_j, p_k, p_l \rangle
             else \mathcal{N} \leftarrow \mathcal{N} \cup \langle p_i + 2, p_j, p_k, p_l \rangle
             if p_j - 1 \neq mp then \mathcal{N} \leftarrow \mathcal{N} \cup \langle p_i, p_j - 1, p_k, p_l \rangle
             else \mathcal{N} \leftarrow \mathcal{N} \cup \langle p_i, p_j - 2, p_k, p_l \rangle
             if p_j + 1 \neq mp then \mathcal{N} \leftarrow \mathcal{N} \cup \langle p_i, p_j + 1, p_k, p_l \rangle
             else \mathcal{N} \leftarrow \mathcal{N} \cup \langle p_i, p_j + 2, p_k, p_l \rangle
      for s' \in \mathcal{N} do
             if p_i = p_j and p_i \neq 0 then \mathcal{N} \leftarrow \mathcal{N} \setminus s' \cup \langle 0, 0, p_k, p_l \rangle
             if p_k = p_l and p_k \neq l then \mathcal{N} \leftarrow \mathcal{N} \setminus s' \cup \langle p_i, p_j, l, l \rangle
      for s' \in \mathcal{N} do
          if !AllowedState(s') then \mathcal{N} \leftarrow \mathcal{N} \setminus s'
      return {\mathcal N}
Function AllowedState(s')
       \langle p_i, p_j, p_k, p_l \rangle \leftarrow s'
      if !(0 \le p_i \le p_j \le p_k \le p_l \le l \text{ and } p_k \ge m) then return False
      if p_i = p_j and p_k = p_l then return False
       // Further prune the state space
      if (0 < m < p_k) and (p_i \neq 0 \text{ or } p_i < p_k - 5) then return False
      if p_k - p_i > m + 4 then return False
      return True
```

and complex2 are completely bound except in their toeholds (have formed the complex helix), reporter1 and reporter2 are completely bound except in their toeholds (have formed the reporter helix), and no base pairs have formed between the complex helix and the reporter helix. Hence, each helix has two complementary strands except for their toeholds. In the final state ($S_{final} = \{\langle 0, 0, l+m, l+n, 0, 0 \rangle \}$), the reporter and complex helices have completely exchanged strands and two new helices, which have complementary strands, are formed.

Algorithm 9: Find possible neighbors of a toehold-mediated 4-way strand exchange state s

```
Function NeighborStates (s)
      \langle p_i, p_j, p_{i'}, p_{j'}, p_k, p_l \rangle \leftarrow s, \mathcal{N} \leftarrow \emptyset
      if p_i = p_{i'} then

C Half Context Frequency

Fig. 1 (Fig. 2) shows the frequency with which half contexts are encountered in unimolecular (bimolecular) transitions during one iteration of training the MAP or the MCMC approach.

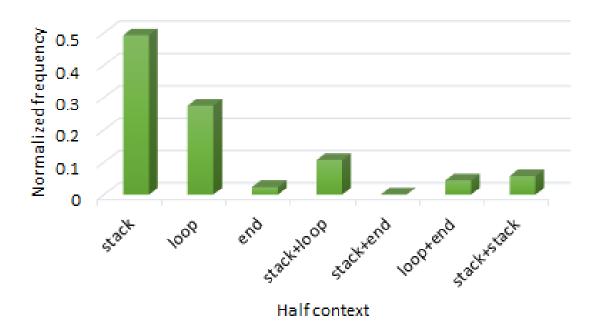

Fig. 1: Normalized frequency of the half contexts in unimolecular transitions.

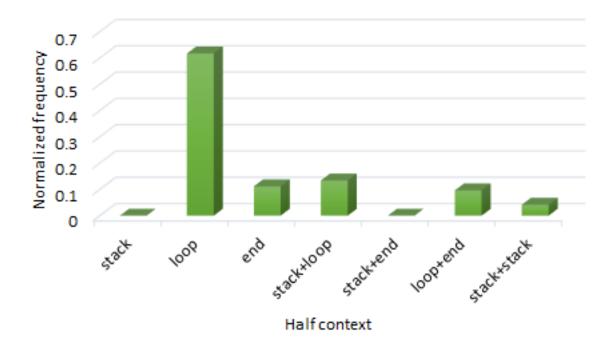

Fig. 2: Normalized frequency of the half contexts in bimolecular transitions.

D Experimental Plot Reproduction

The following plots show how the performance of the Metropolis and the Arrhenius models on the training and testing datasets. Dashed lines indicate model fits and predictions and solid lines indicate experimentally determined values. For the MCMC ensemble method, error bars indicate the range (minimum to maximum) of predictions.

D.1 Training Set (\mathcal{D}_{train})

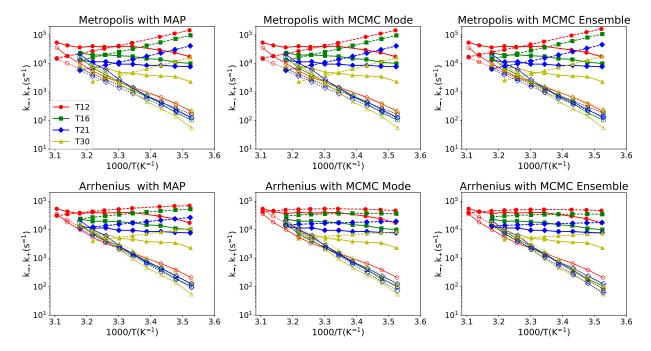

Fig. 3: Model fitting (dashed lines) of reaction rate constants (y axis) for hairpin closing (solid) and opening (open) with sequence 5'-CCCAA- $(T)_n$ -TTGGG-3' where n is 12,16, 21, or 30, experimental data (solid lines) from Fig. 4 of Bonnet et al. [3].

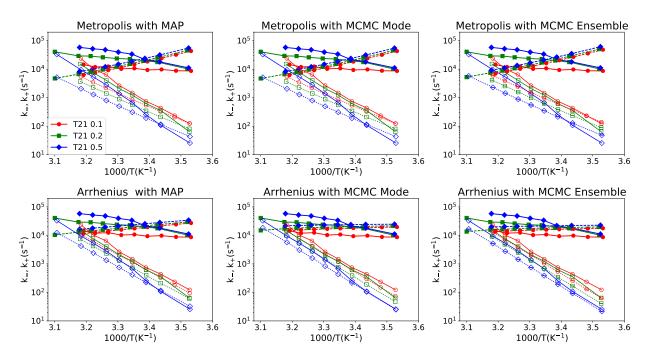

Fig. 4: Model fitting (dashed lines) of reaction rate constants (y axis) for hairpin opening (open) and closing (solid) with sequence 5'-CCCAA- $(T)_{21}$ -TTGGG-3' at different salt concentrations, Fig. 6 from Bonnet et al. [3]. experimental data (solid lines) from Fig. 6 of Bonnet et al. [3] wrongfully notes the use of a poly-A instead of a poly-T hairpin loop, which becomes evident in comparison to Fig. 5 of the same work (private communication with the authors).

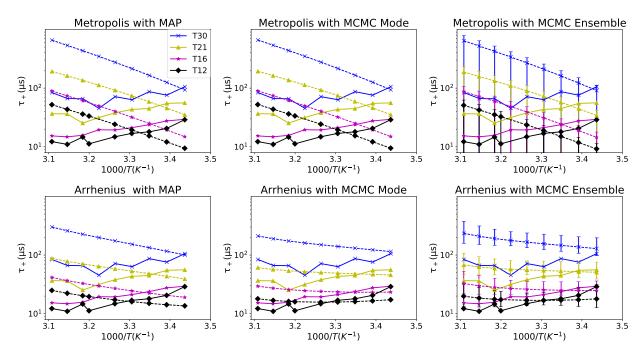

Fig. 5: Model fitting (dashed lines) of reaction timescales (y axis) for hairpin closing with sequence 5'-CCCAA- $(T)_n$ -TTGGG-3' where n is 12,16, 21, or 30, experimental data (solid lines) from Fig. 3.28 of Bonnet [2].

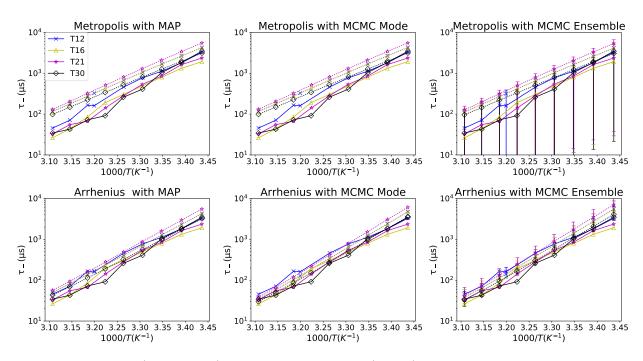

Fig. 6: Model fitting (dashed lines) of reaction timescales (y axis) for hairpin opening with sequence 5'-CCCAA- $(T)_n$ -TTGGG-3' where n is 12,16, 21, or 30, experimental data (solid lines) from Fig. 3.28 of Bonnet [2].

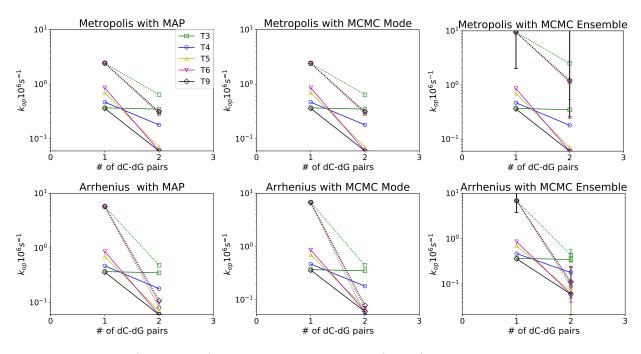

Fig. 7: Model fitting (dashed lines) of reaction rate constants (y axis) for hairpin opening with sequence $F-(dC)_y-(dT)_x-(dG)_y$ (x ranging from 3 to 9) as a function of dC-dG pairs (y ranging from 1 to 2), experimental data (solid lines) from Table 1 (Fig. 3b) of Kim et al. [5].

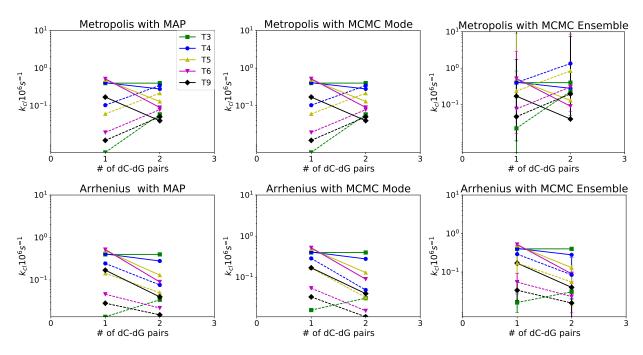

Fig. 8: Model fitting (dashed lines) of reaction rate constants (y axis) for hairpin closing with sequence $F-(dC)_y-(dT)_x-(dG)_y$ (x ranging from 3 to 9) as a function of dC-dG pairs (y ranging from 1 to 2), experimental data (solid lines) from Table 1 (Fig. 3b) of Kim et al. [5].

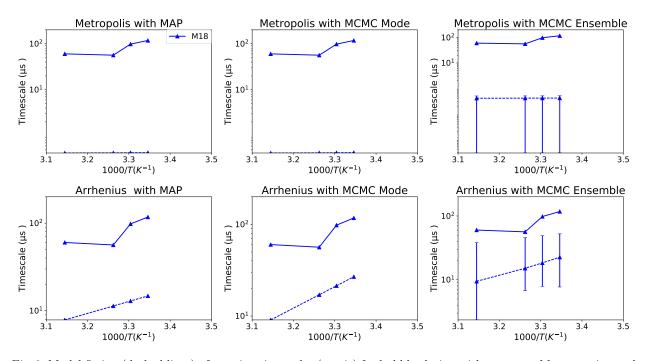

Fig. 9: Model fitting (dashed lines) of reaction timescales (y axis) for bubble closing with sequence M_{18} , experimental data (solid lines) from Fig. 4 of Altan-Bonnet et al. [1].

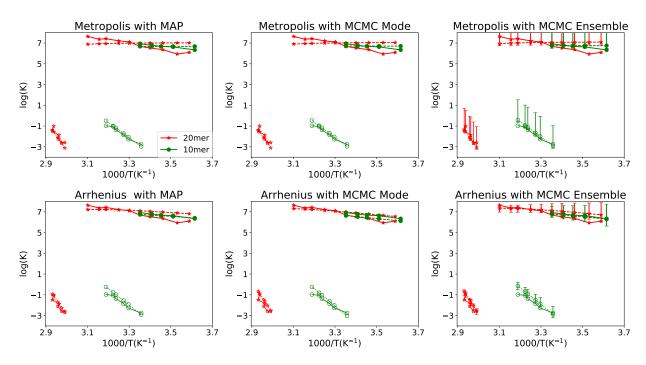

Fig. 10: Model fitting (dashed lines) of reaction rate constants (y axis) for helix association (solid) and disassociation (solid), experimental data (solid lines) from Fig. 6 of Morrison and Stols [7]. 10mer and 20mer are variation in the length of the strand.

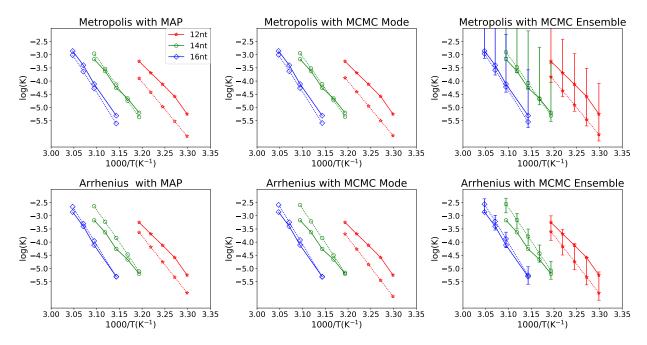

Fig. 11: Model fitting (dashed lines) of of reaction rate constants (y axis) for helix disassociation, experimental data (solid lines) from Fig. 6 of Reynaldo et al. [8]. 12nt, 14nt, and 16nt are variations in the length of the strand.

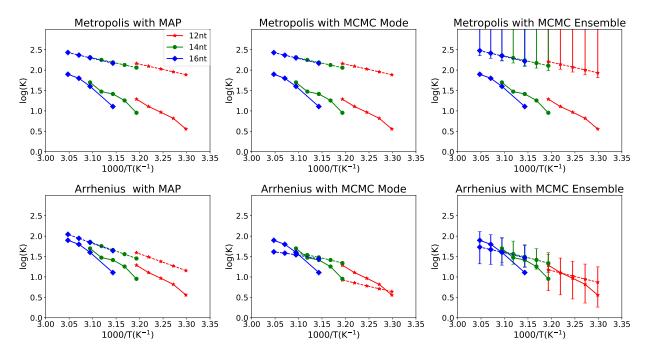

Fig. 12: Model fitting (dashed lines) of reaction rate constants (y axis) for toehold-mediated 3-way strand displacement, experimental data (solid lines) from Fig. 6 of Reynaldo et al. [8]. 12nt, 14nt, and 16nt are variations in the length of the strand.

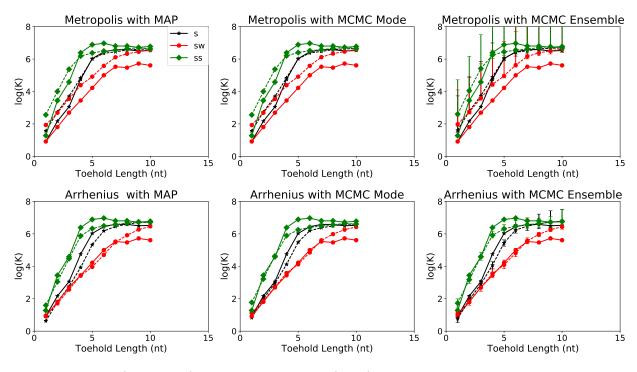

Fig. 13: Model fitting (dashed lines) of reaction rate constants (y axis) for toehold-mediated 3-way strand displacement, experimental data (solid lines) from Fig. 3b of Zhang and Winfree [9]. The toehold is varied between strong (ss), regular (s) and weak (sw) binding strength by varying the G/C content of the toehold sequence.

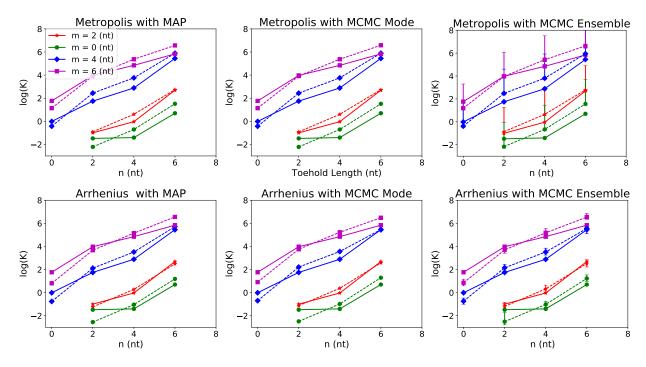

Fig. 14: Model fitting (dashed lines) of reaction rate constants (y axis) for toehold-mediated 4-way strand exchange, experimental data (solid lines) from Table 5.2 of Dabby [4]. m (shown on the legend) and n (shown on the x-axis) are variations in the length of the toehold domains (see Appendix B.5).

D.2 Testing Set $(\mathcal{D}_{\text{test}})$

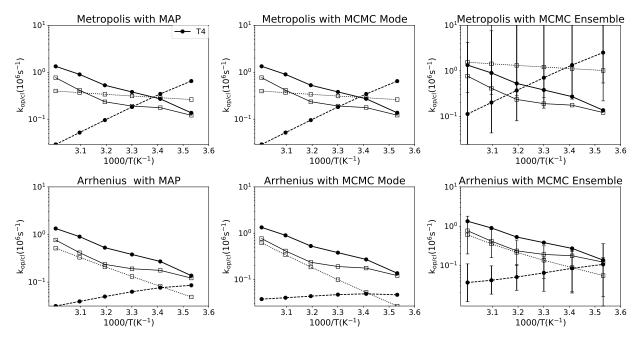

Fig. 15: Model predictions (dashed lines) of reaction rate constants (y axis) for hairpin closing (solid) and opening (open) with sequence $F_{-}(dC)_{2-}(dT)_{4-}(dG)_{2}$, experimental data (solid lines) from Fig. 5a of Kim et al. [5].

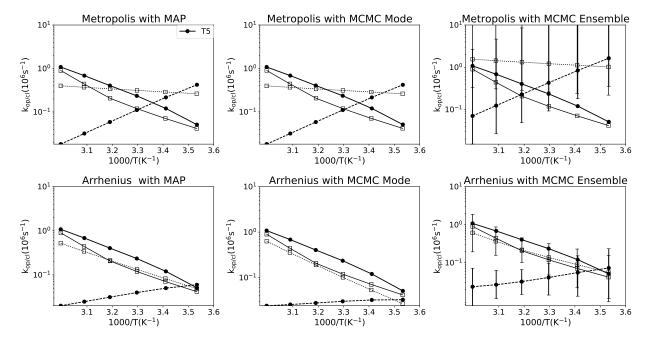

Fig. 16: Model predictions (dashed lines) of reaction rate constants (y axis) for hairpin closing (solid) and opening (open) with sequence F- $(dC)_2$ - $(dT)_5$ - $(dG)_2$, experimental data (solid lines) from Fig. 5b of Kim et al. [5].

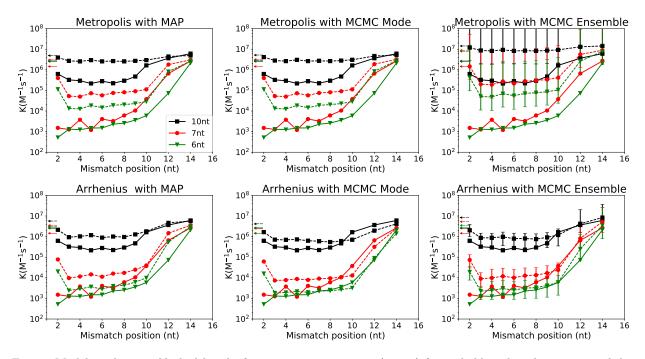

Fig. 17: Model predictions (dashed lines) of reaction rate constants (y axis) for toehold-mediated 3-way strand displacement with mismatches, experimental data (solid lines) from Fig. 2d of Machinek et al. [6]. For the MCMC ensemble method, error bars indicate the range (minimum to maximum) of predictions. Arrows indicate no mismatch. The mismatch in the invading strand affects the reaction rate. The length of the toehold domain is ten, seven, and six nucleotides long for \blacksquare , \bullet , and \blacktriangledown , respectively.
